(54) **Map kinase kinases (MEK)**

(57) A mitogen-activated protein (MAP) kinase kinase gene, tMEK2, was isolated from tomato cv. Bonny Best. By mutagenesis, a permanently-active variant, tMEK2^{MUT}, was created. Both wild type tMEK2 and mutant tMEK2^{MUT} were driven by a strong constitutive promoter, tCUPΔ, in a tomato protoplast transient expression system. Pathogenesis-related genes, PR1bl and PR3, and a wound-inducible gene, ER5, were activated by tMEK2^{MUT} expression revealing the convergence of the signal transduction pathways for pathogen attack and mechanical stress at the level of MAPKK. Activation of biotic and abiotic stress response genes downstream of tMEK2 occurred through divergent pathways involving at least two classes of mitogen-activated protein kinase. This study shows that tMEK2 may play an important role in the interaction of signal transduction pathways that mediate responses to both biotic (eg disease) and abiotic (wound responsiveness) stresses.

EP 1 078 985 A2

Description

[0001] The present invention relates to a derivative of a mitogen-activated protein (MAP) kinase kinase and the use of said derivative for increasing disease resistance and enhanced stress tolerance in plants.

BACKGROUND OF THE INVENTION

[0002] Signaling mechanisms that mediate plant defense responses may be strongly conserved among plants. This is supported by the observation that several classes of R genes confer disease resistance when expressed in heterologous plant species. For instance, the tomato disease resistance gene, *Cf-9,* was shown to confer responsiveness to the fungal avirulence gene product *Avr9* in transgenic tobacco and potato (Hammond-Kosack *et al.*, 1998). Although *Cladosporium fulvum* is exclusively a fungal pathogen of tomato, a rapid hypersensitive response (HR) was induced in transgenic tobacco and potato by experimentally allowing these specific interactions to occur which then induced signaling pathways that could be common to the plants. Furthermore, the tomato disease resistance gene, *Pto,* which specifies race-specific resistance to the bacterial pathogen *Pseudomonas syringae pv tomato* carrying the *avrPto* gene, also increased the resistance of tomato to *Xanthomonas campestris pv vesicatoria* and *Cladosporium fulvum* when over expressed (Tang *et al.*, 1999). Clearly, it is the recognition of the pathogen that is unique to most plant species; whereas, the defense response is similar among them.

[0003] Considerable progress has now been made in understanding the signal transduction pathways following perception of biotic and abiotic stresses and the information is being used to develop strategies for modifying transgenic plants. Separate manipulations of the G protein pathway (Xing *et al.*, 1996, 1997) may elevate pathogen resistance or induce defense reactions in transgenic tobacco (Beffa *et al.*, 1995) and increase resistance to tobacco mosaic virus infection (Sano *et al.*, 1994). Multiple roles for MAPK (mitogen-activated protein kinase) in plant signal transduction have also been shown, including responsiveness to pathogens, wounding and other abiotic stresses, as well as plant hormones such as ABA, auxin and ethylene (Hirt, 1997; Kovtun *et al.*, 1998). MAPKK (mitogen-activated protein kinase kinase) from Arabidopsis (AtMEK1) and tomato (LeMEK1) have been shown to be induced by wounding (Morris *et al.*, 1997; Hackett *et al.*, 1998), and the maize (ZmMEK1) gene was induced by high salinity and cold (Hardin and Wolniak, 1998). These enzymes interact within MAP kinase pathways that are extensively used for transcytoplasmic signaling to the nucleus. In the MAPK signal transduction cascade, MAPKK (MAP kinase kinase) is activated by upstream MAPKKK (mitogen-activated protein kinase kinase kinase) and in turn activates MAPK. The transcription of specific genes is induced by MAPK through phosphorylation and activation of transcription factors. This pathway has not yet been manipulated in plants.

SUMMARY OF THE INVENTION

[0004] The present invention relates to a derivative of a mitogen-activated protein (MAP) kinase kinase and the use of said derivative for increasing disease resistance and enhanced stress tolerance in plants.

[0005] According to the present invention it was determined that mutagenesis of a core phosphorylation site of a member of the MAPK cascade can create a permanently-active form, which stimulates both pathogen- and wound-inducible genes when introduced into plant cells.

[0006] Thus, according to the present invention there is provided a nucleic acid sequence encoding a derivative of a mitogen-activated protein kinase kinase gene from plants, wherein said derivative contains a negative charge in a core phosphorylation site of said protein kinase kinase gene.

[0007] Further according to the present invention there is provided a derivative of a mitogen-activated protein kinase kinase gene from plants, wherein said derivative contains a negative charge in a core phosphorylation site of said protein kinase kinase gene.

[0008] In a further embodiment of the present invention there is provided a cloning vector comprising a nucleic acid sequence encoding a derivative of a mitogen-activated protein kinase kinase gene from plants, wherein said derivative contains a negative charge in a core phosphorylation site of said protein kinase kinase gene.

[0009] The present invention also includes a transgenic plant comprising a nucleic acid sequence encoding a derivative of a mitogen-activated protein kinase kinase gene, wherein said derivative contains a negative charge in a core phosphorylation site of said protein kinase kinase gene.

[0010] Further, according to the present invention there is provided a method of increasing disease resistance or enhancing stress tolerance in a plant by introducing into said plant a nucleic acid sequence encoding a derivative of a mitogen-activated protein kinase kinase gene, wherein said derivative contains a negative charge in a core phosphorylation site of said protein kinase kinase gene.

BRIEF DESCRIPTION OF THE DRAWINGS

[0011] These and other features of the invention will become more apparent from the following description in which reference is made to the appended drawings wherein:

[0012] **FIGURE 1** shows sequence analysis of tMEK2. **FIGURE 1a** shows the DNA (SEQ ID NO:1) and deduced amino acid sequence (SEQ ID NO: 2). Roman numerals under the sequence indicate the 11 subdomains found in protein kinases. The asterisk indicates stop codon. **FIGURE 1b** shows the alignment of the deduced amino acid sequences from catalytic domains of MAPKK subfamily members (SEQ ID NO: 3 to 21). **FIGURE 1c** shows the alignment of amino acid sequences of tMEK2 with other MAPKKs between subdomain VII and VIII. Dashes represent gaps introduced for maximum matching. The amino acid residues in bold and italics between subdomain VII and VIII show putative phosphorylation sites.

[0013] **FIGURE 2** shows the autophosphorylation and substrate phosphorylation activity of tMEK2. **FIGURE 2a** shows the autophosphorylation of tMEK2^{WT} and tMEK^{MUT}. Recombinant GST-tMEK2^{WT} or GST-tMEK2^{MUT} proteins were incubated *in vitro* without any protein kinase substrate followed by SDS-PAGE and autoradiography. **FIGURE 2b** shows the phosphorylation of myelin basic protein (MBP) by tMEK2^{WT} and tMEK^{MUT}. Recombinant GST-tMEK^{WT} or GST-tMEK2^{MUT} proteins were incubated *in vitro* with MBP followed by SDS-PAGE and transfer to nitrocellulose. The upper panel is the autoradiography of the nitrocellulose filter. The lower panel is the immunoblot with anti-GST antibody.

[0014] **FIGURE 3** shows the constructs of tMEK2^{WT} or tMEK^{MUT} driven by the constitutive promoter tCUPΔ or control plasmid showing GUS gene driven by the constitutive promoter tCUPΔ.

[0015] **FIGURE 4** shows the expression of tMEK2 in tomato leaf mesophyll protoplasts. The effect was analysed by quantitative RT-PCR following transient expression of tMEK2 in protoplasts. C1, no electroporation; C2, electroporation of control plasmid; MEK2^{WT}, electroporation of plasmid with tMEK2^{WT} driven by the tCUPA promoter, electroporation of plasmid with tMEK2^{MUT} driven by tCUPΔ promoter. The pathogenesis-related genes PR1b1, PR3 and Twil were tested. Tomato actin was used as an internal standard.

[0016] **FIGURE 5** shows the activation of ER5 by tMEK2. **FIGURE 5a** shows RNA gel blot analysis of total RNA (15 μg) from leaves following wounding for the indicated time in hours, showing wound-induced activation of tMEK2 and ER5 genes. **FIGURE 5b** shows the activation of ER5 gene by tMEK2. The effect was analysed by quantitative RT-PCR following transient expression of tMEK2 in protoplasts: Lane settings are as described in Figure 4. Tomato actin was used as an internal standard.

[0017] **FIGURE 6** shows the effect of MAPK inhibitors on tMEK2^{MUT}-induced gene activation. Kinase inhibitors at the concentration of 1 μM for staurosporine, 350 nM for SB 202190 and 1 μM for PD 98059, SB 203580 and SB 202474 were included in the proteoplast incubation buffer.

[0018] **FIGURE 7** shows the comparison of disease symptoms on a leaf from a wild type plant and on a leaf from tMEK2^{MUT} transformed plant.

DESCRIPTION OF PREFERRED EMBODIMENT

[0019] According to the present invention there is provided a derivative of a mitogen-activated protein kinase kinase (MAPKK). The present invention also relates to a method for increasing disease resistance and enhanced stress tolerance in plants using said derivative.

[0020] When used herein the term derivative means a modified MAPKK protein, wherein said modification includes the replacement of one or more amino acids of the wild type MAPKK with one or more other amino acids. Therefore said derivative is a non-naturally occurring variant of the wild type MAPKK.

[0021] MAPK signaling cascades are ubiquitous among eukaryotes from yeast to human (Guan, 1994) and mediate a large array of signal transduction pathways in plants (Hirt, 1997; Mizoguchi *et al.*, 1997). The cascades utilize the reversible phosphorylation of regulatory proteins to achieve rapid biochemical responses to changing external and internal stimuli. A specific MAPK is rapidly activated by pathways responding to cold, drought, mechanical stimuli and wounding (Bogre *et al.*, 1997; Jonak *et al.*, 1996; Seo et al., 1995; Usami *et al.*, 1995). MAPKs are also rapidly activated by pathways responding to pathogen elicitors (Ligterink *et al.*, 1997; Suzuki and Shinshi, 1995). Other factors such as salicylic acid which is a signaling molecule in the pathogen response, may intervene in the signal cascade by transiently activating a MAPK in tobacco cells (Zhang and Klessig, 1997). MAPKK, which activates MAPK by phosphorylation in the signal cascade has been identified in Arabidopsis, tobacco, maize and tomato (Mizoguchi *et al.*, 1997; Shibata *et al.*, 1995; Hardin and Wolniak, 1998). Although phosphorylation of MAPKK by MAPKKK is the primary mechanism for initiating the signal cascade, regulation at the level of gene expression has also been implied. For instance, transcriptional activity of an Arabidopsis MAPKK, *MEK1* (Morris *et al.*, 1997), and a tomato MAPKK, *tMEKI (Hackett et al.*, 1998), was increased by wounding. Transcriptional activity of ZmMEK1, a maize MAPKK, was slightly increased in roots by high salinity and was substantially decreased by cold (Hardin and Wolniak, 1998). In this study, tomato tMEK2 mRNA accumulation was also induced by wounding of leaves but transient expression in protoplasts did not result in

the activation of the target gene ER5. This observation supported the view that biochemical activation of MAPKK by phosphorylation was the primary factor in signal transduction and that transcriptional control plays a secondary role.

[0022] Yeast and animal MAPKK are activated when serine and serine/threonine residues in the SxAxS/T motif, located upstream of the subdomain VIII are phosphorylated by MAPKKK. The putative consensus motif for characterised plant MAPKK is a S/TxXXxxS/T signature. This motif contains two additional residues when compared with the motif SxAxS/T detected in other eukaryotes. Thus, according to the present invention the use of a plant gene encoding the MAPKK is preferred to that of the yeast and animal genes, as the plant gene provides additional sites for manipulation. The plant genes also provide additional combinations of sites that can be modified according to the present invention. Thus, according to the present invention one or multiple sites of the plant gene can be modified.

[0023] According to the present invention, by creating a negative charge around a core phosphorlyation site the activation by MAPKKK was not needed for MAPKK activity.

[0024] According to the present invention possible core phosphorlyation sites include: serine and/or threonine sites located upstream of the subdomain VIII.

[0025] According to the present invention the creation of a negative charge around one of said core phosphorlyation sites includes replacement of one or more amino acids with an amino acid selected from the group consisting of: any negatively charged amino acids. In one embodiment of the present invention said negatively charged amino acids include glutamic acid and aspartic acid.

[0026] In one embodiment of the present invention MAPKK gene, from various sources can be modified, as described above. As noted earlier MAPK signalling cascades are ubiquitous among eukaryotes from yeast to human. Suitable examples of a suitable gene that can be used according to the present invention include *Lycopersicum esculentum* cv Bonny Best, tMEK2, together with other genes available in the art, as exemplified by the following:

wherein the amino acid numbering system is based on the tomato gene tMEK2.

[0028] In one further embodiment of the present invention, there is provided a derivative of a mitogen-activated protein kinase kinase gene from tomato cv. Bonny Best, wherein the amino acids serine221 and threonine226 have been replaced with aspartic acid.

[0029] Methods of modifying amino acid sequences are well known in the art. In general terms two primers, one for the 3' end and one for the 5' end are used to amplify the coding region. PCR-based site-directed mutagenesis was then done using the procedure as described by Higuchi (1989). Based on the sequence of the PCR product two PCR reactions are used for its mutagenesis. In PCR reaction 1, a primer containing the appropriate base substitution was used together with the 5' primer to amplify the 5' end of the coding region. In PCR reaction 2, a further primer with the appropriate base substitution was used together with the 3' primer to amplify the 3' end of the coding region. Products from both reactions were then purified and combined for 3' extension. The resulting mutant was then amplified with the original 3' and 5' primers.

[0030] The present invention also includes a suitable cloning vector containing the nucleic acid sequence encoding the derivative of the MAPK gene for transforming suitable plant recipients to increase disease resistance and enhance stress tolerance in plants. Suitable cloning vectors include any cloning vectors, Ti plasmid-derived and standard viral vectors well known in the art.

[0031] The cloning vectors can include various regulatory elements well known in the art. For example the cloning vector of the present invention can further comprise a 3' untranslated region. A 3' untranslated region refers to that

portion of a gene comprising a DNA segment that contains a polyadenylation signal and any other regulatory signals capable of effecting mRNA processing or gene expression. The polyadenylation signal is usually characterized by effecting the addition of polyadenylic acid tracks to the 3' end of the mRNA precursor. Polyadenylation signals are commonly recognized by the presence of homology to the canonical form 5' AATAAA-3' although variations are not uncommon.

[0032] Examples of suitable 3' regions are the 3' transcribed non-translated regions containing a polyadenylation signal of *Agrobacterium* tumor inducing (Ti) plasmid genes, such as the nopaline synthase (*Nos* gene) and plant genes such as the soybean storage protein genes and the small subunit of the ribulose-1, 5-bisphosphate carboxylase (ss-RUBISCO) gene.

[0033] The cloning vector of the present invention can also include further enhancers, either translation or transcription enhancers, as may be required. These enhancer regions are well known to persons skilled in the art, and can include the ATG initiation codon and adjacent sequences. The initiation codon must be in phase with the reading frame of the coding sequence to ensure translation of the entire sequence. The translation control signals and initiation codons can be from a variety of origins, both natural and synthetic. Translational initiation regions may be provided from the source of the transcriptional initiation region, or from the structural gene. The sequence can also be derived from the promoter selected to express the gene, and can be specifically modified so as to increase translation of the mRNA.

[0034] To aid in identification of transformed plant cells, the constructs of this invention may be further manipulated to include plant selectable markers. Useful selectable markers include enzymes which provide resistance to chemicals such as an antibiotic such as gentamycin, hygromycin, kanamycin, or herbicides such as phosphirothycin, glyphosate, chlorsulturam and the like. Similarly, enzymes providing for production of a compound identifiable by colour change such as *GUS* (β-glucuronidase), or luminescence, such as luciferase are useful.

[0035] A promoter, included in the cloning vector of the present invention, can include a constitutive promoter, which will ensure continued expression of the gene. The nucleic acid sequence encoding the derivative of the MAPK gene can also be under the control of a inducible promoter. Said inducible promoter is triggered by an induction response.

[0036] Generally speaking, an inducible promoter is a promoter that is capable of directly or indirectly activating transcription of one or more DNA sequences or genes in response to an inducer. In the absence of an inducer the DNA sequences or genes will not be transcribed. Typically the protein factor, that binds specifically to an inducible promoter to activate transcription, is present in an inactive form which is then directly or indirectly converted to the active form by the inducer. The inducer can be a chemical agent such as a protein, metabolite, growth regulator, herbicide or phenolic compound or a physiological stress imposed directly by heat, cold, salt, or toxic elements or indirectly through the action of a pathogen or disease agent such as a virus. A plant cell containing an inducible promoter may be exposed to an inducer by externally applying the inducer to the cell or plant such as by spraying, watering, heating or similar methods.

[0037] A constitutive promoter directs the expression of a gene throughout the various parts of a plant and continuously throughout plant development. Examples of known constitutive promoters include those derived from the CaMV 35S and *Agrobacterium* Ti plasmid opine synthase gene (Sanders *et al.,* 1987) or ubiquitin (Christensen *et al.,* 1992). Additionally the constitutive promoter described in WO 97/28268 published August 7, 1997.

[0038] Also considered part of this invention are transgenic plants containing the variant of the present invention. Methods of regenerating whole plants from plant cells are known in the art, and the method of obtaining transformed and regenerated plants is not critical to this invention. In general, transformed plant cells are cultured in an appropriate medium, which may contain selective agents such as antibiotics, where selectable markers are used to facilitate identification of transformed plant cells. Once callus forms, shoot formation can be encouraged by employing the appropriate plant hormones in accordance with known methods and the shoots transferred to rooting medium for regeneration of plants. The plants may then be used to establish repetitive generations, either from seeds or using vegetative propagation techniques.

[0039] Besides viral cloning vectors, transformation can also be accomplished by particle bombardment using the nucleic acid sequence encoding the derivative of the MAPK gene. Bondardment is a DNA delivery technique using foreign DNA particles delivered to various plant cells, tissues and species using biolistic device such as gun powder-driven biolistic device (Dupont, Wilmington, DE), gas-driven particle delivery system, microtargeting particle accelator, an air gun apparatus (Daniell, 1997), helium blasting (Pareddy et al., 1997) and instruments based on electric discharge. Transformation can also be achieved by direct uptake of Agrobacterium that contained foreign DNA sequence into plants via stomato in the leaves of stem or roots (Clough et al., 1998).

[0040] A further aspect of the present invention is directed to the use of said nucleic acid sequence encoding the derivative of the MAPK gene to increase disease resistance or to enhance stress tolerance in plants. In this aspect of the invention the nucleic acid is introduced into the plant using any of the methods described above.

[0041] Pathogenesis-related (PR) proteins are intra- and extracellular proteins that accumulate in plant tissues or cultured cells after pathogen attack or elicitor treatment (Bowles, 1990). Using PR gene expression as a marker for the plant defence response, both PR1b1 and the chitinase gene were induced by the derivative of the MAPK gene of

the present invention.

[0042] Furthermore, according to the present invention, the transcription of the tomato ER5 gene, ZG (ABA). drought and wounding (Zegzouti *et al.*, 1997) was induced by the derivative of the MAPK gene of the present invention.

[0043] Thus, according to the present invention the derivative of the MAPK gene of the present invention can activate both pathogen- and wound-related genes.

[0044] The use of said nucleic acid sequence encoding the derivative of the MAPK gene can also be used in combination with other methods to increase disease resistance or to enhance stress tolerance in plants. These other methods could include modification of downstream components for example transcription factors and transcriptional activators. The modification of transcription factors was proven to be an effective means to improve plant stress tolerance. Overexpression of a single stress-inducible transcription factor DREB1A isolated from Arabidopsis improved plant drought, salt, and freezing tolerance (Masuga et al., 1999). Overexpression of CBF1, an Arabidopsis transcriptional activator, enhanced freezing tolerance (Jaglo-Ottosen et al., 1998). There is potential that modification of transcription factors or transcriptional activators downstream of MAPK in our system will enhance disease resistance and stress tolerance.

[0045] In addition there are some parallel pathways that could contribute to increased disease resistance or to enhanced stress tolerance in plants if used in combination with the modified MAPK pathway of the present invention. An example of another parallel pathway would be calcium dependent protein kinase (CDPK) (Sheen, 1996). CPDK has also been shown to act as a key mediator for cold, salt, drought, dark and ABA stresses. In addition CDPK is involved in primary defence response to pathogen attack. Overexpression of either of two different CDPKs (ATCDPK1 and ATCDPK1a) in maize protoplasts active stress signalling (Sheen, 1996). Thus the co-manipulation of the two pathways should further strengthen the defence ability of the plant.

[0046] The present invention is illustrated by the following examples, which are not to be construed as limiting.

EXAMPLES

Example 1: Isolation and Modification of tMEK2.

[0047] RNA was extracted with Extact-A-Plant™ RNA Isolation Kit (CloneTech Laboratories, Inc.) from four-week-old tomato leaves. Reverse transcription was as described in Sambrook *et al.* (1989). Cloning was carried out by PCR using Taq DNA polymerase (Life Technologies Inc.). A MAPKK gene, tMEK2, was isolated from tomato cv. Bonny Best by PCR (Figure la) using published MAPKK gene sequences of tomato cv. Ailsa Craig and other plant species. It shares a high level of sequence homology with MAPKKs from other species and tomato cultivars (Figure 1b) but compared with MAPKKs from mammals and yeast, tMEK2 and other plant MAPKKs have two more potential core phosphorylation sites between subdomains VII and VIII (Figure 1c).

[0048] Using PCR-assisted, site-directed mutagenesis, amino acids serine221 and threonine226 were replaced with aspartic acid (Figure 1c) creating a negative charge around the core phosphorylation site so that phosphorylation of MAPKK by upstream MAPKKK is no longer necessary for activity. Two primers (5'-end and 3'-end) that span the coding region of tomato cv Ailsa Craig LeMEK1 were used for the amplification of the MAPKK coding sequence in tomato cv Bonney Best. PCR-based site-directed mutagenesis was carried out as described before (Higuchi, 1989). Based on the sequence of the PCR product, two PCR reactions were run for its mutagenesis. In PCR reaction 1. a primer containing the base substitutions (5'GTATGTGCCGACAAA GTCATTGGCCAGTCCATCTGTGCTT-GCTAGTACTGCACTCACAC3'.SEQ ID NO: 22) was used together with 5'-end primer to amplify a 692 bp fragment corresponding to the 5' region of the cloned MAPKK. In PCR reaction 2, a primer containing the base substitutions (5'GTACTAGCAAGCACAGATGGACTGGCCA ATGACTTTGTCGGCACATACAACTATATGTC3', SEQ ID NO:23) was used together with 3'-end primer to amplify a 429 bp fragment corresponding to the 3'.region of the cloned MAPKK. Products from PCR reaction 1 and 2 were then purified and combined for 3' extension. Mutant tMEK2 was amplified with the original 5'-end primer containing *BamHI* and *NcoI* restriction sites, and 3'-end primer containing *SalI* and *SmaI* restriction sites. The wild type and mutagenized PCR products were purified from an agarose gel using Elu-Quik DNA Purification Kit (Schleicher & Schuell) and ligated into pre-digested pGEM-T Easy vector. The inserts were digested using *NcoI/SmaI* and ligated into pTZ19 tCUPA-GUS-nos3'. This derivative of tCUP promoter was created by the following modifications to the original tCUP: mutation of the sequence, 3' deletion of the sequence, nucleotide addition to the sequence, deletion of an upstream out-of-frame ATG methionine initiator codon from the sequence, deletion of the fusion protein encoded by the tobacco genomic DNA from the sequence, addition of restriction sites to the sequence. In detail, exact nucleotide changes are (numbered relative to the tCUP sequence or to the tCUPΔ (sequence as noted): 2084 CATATGA 2090 (NdeI recognition site beginning at 2084 underlined) in the tCUP sequence mutated to 2084 CATAGATCT 2092 (BglII recognition site beginning at 2087 underlined) in the tCUPΔ sequence deleting one restriction site and one upstream out-of-frame ATG methionine initiator codon while adding another restriction site and two nucleotides; 2171 AATACATGG 2179 in the tCUP sequence mutated to 2173 CCACCATGG 2181 in the tCUPΔ sequence

adding a Kozak consensus motif for translational initiation and an NcoI recognition site at 2176 underlined); 2181 to 2224 (relative to tCUP sequence) of tobacco genomic DNA removed from tCUPA (2183 to 2226 relative to tCUPA), deleting the 3' end of the tCUP sequence and the N-terminal fusion peptide encoded by the tobacco genomic DNA. The tCUPΔ-GUS-nos construct was created by fusion of the tCUPA sequence with a GUS gene and nos terminator having the sequence 2183 CTCTAGAGGAT CCCCGGGTGGTCAGTCCCTT 2213 3' (SEQ ID NO:24) to the GUS ATG at 2214 on the tCUPΔ sequence (see Figure 3).

Example 2: Expression and Phosphorylation Analysis of Recombinant tMEK2

[0049] For in-frame cloning with GST into the *BamHI/SalI* sites in the pGEX-4T-3 vector (Amersham Pharmacia) subcloned PCR products in pGEM-T Easy vector were digested by *BamHI/SalI* and ligated into pGEX-4T-3 cut with the same enzymes. Sequences of cloned products were confirmed by DNA sequencing. The proteins were expressed as glutathione-S-transferase fusions (GST) and purified by glutathione-agarose (Sigma) affinity chromatography essentially as described in manufacturer's protocol. Protein concentration was determined with a Bio-Rad detection system (Bio-Rad).

[0050] Autophosphorylation assay contained 1μg of GST-tMEK2^{WT} or GST-tMEK2^{MUT} in 30 mM Hepes (pH 7.5), 5 mM of $MgSO_4$, 5 mM of $MnSO_4$, and 1mM $CaCl_2$, 10 mM ATP, and 3 μCi γ-^{32}P-ATP (specific activity 222 TBq/mmol) in a total volume of 15 μl. The reaction mixture was incubated at 30°C for 45 min and the reaction was stopped by boiling 3 min in SDS sample buffer. As shown in Figure 2a, both wild type and mutant forms of the tMEK2 enzyme showed autophosphorylation activity.

[0051] Substrate phosphorylation assays contained 1 μg of GST-tMEK2^{WT} or GST-tMEK2^{MUT}, 2 μg of myelin basic protein (MBP, Life Technologies Inc.), 30 mM Hepes (pH 7.5), 5 mM $MgSO_4$ and 5 mM $MnSO_4$. Reactions were carried out at 30°C for 30 min. Phosphorylated products were separated by 10% SDS-PAGE, transferred to nitrocellulose and autoradiographed. Both the wild type and mutant forms of the tMEK2 enzyme phosphorylated myelin basic protein (MPB) *in vitro* (Figure 2b). Protein immunoblotting was performed as described previously (Xing *et al.*, 1996) using antiGST antibody (Amershan Pharmacia) and alkaline phosphatase-conjugated secondary antibody.

Example 3: Activation of pathogen- and wound-related genes by tMEK2

[0052] To examine the effects of tMEK2^{WT} and tMEK2^{MUT} on the activation of pathogenesis-related (PR) or other pathogen-inducible genes a tomato protoplast transient expression system was developed. Chimeric genes, tCUPA -tMEK2^{WT}-nos and tCUPΔ-tMEK2^{MUT}-nos, were constructed using the strong constitutive promoter, tCUPΔ, which was derived from the tCUP promoter as by modification of the mRNA leader sequence described above. After electroporation, transient expression of potential target genes was detected by quantitative RT-PCR. The genes analysed included PR1b1, which is activated by tomato mosaic virus (Tornero *et al.*, 1997); PR3 (chitinase), which is activated during an incompatible C. fulvam-tomato interaction (Danhash *et al.*, 1993); and Twi, which is a pathogen- and would-inducible gene recently identified in tomato (O'Donnell, *et al.*, 1998).

[0053] The following procedures were used.

Protoplast isolation and transformation

[0054] Tomato *(Lycopersicon esculentum cv* Bonny Best) were grown at 80% relative humidity in peat soil in growth cabinets programmed for 16 hr days at 25°C and 8 hr nights at 22°C. Light intensity was controlled at 25 pE m-2 S-1 emitted from "cool white" fluorescent lamps (Philip Canada, Scarborough, Ontario). The youngest fully expanded leaves were surface sterilized for 5 min in 4% sodium hypochlorite and rinsed three times with sterile water. The lower epidermis was gently rubbed with Carborundum, rinsed with sterile water and leaf fragments of ca. 1cm^2 were floated with exposed surface facing an enzyme solution containing 0.15% macerozyme R_{10} (Yakult Honsha Co., Japan), 0.3% Cellulase "Onozuka" Rio (Yakult Honsha Co., Japan), 0. 4 M sucrose in K3 medium (Maliga et.al., 1973). After overnight incubation at 30 °C, the enzyme-protoplast mixture was filtered through a 100 μm nylon sieve, centrifuged at 500 g for 5 min. and floated protoplasts were collected and washed twice with W5 medium (Maliga et.al., 1973). The protoplasts were kept on ice in W5 medium for 2 hr before transformation.

[0055] The protoplasts were resuspended in electroporation buffer containing 150mM $MgCl_2$ and 0.4 M mannitol at a density of 1x10^6 protoplasts/ml and co-electroporated with 12-15 g of pTZ19 carrying tMEK2 gene and pJD300 carrying luciferase gene in a total volume of 500 μl as described by Leckie (1994) with some modifications. Electroporation was performed at 200 volts and 100 μF (Gene Pulser II, Bio-Rad). Protoplasts were then allowed to recover on ice in the dark for 10 min followed by centrifugation at 500 g for 5 min. After removal of the supernatant, the protoplast pellet, with about 500 μl of buffer, was supplemented with another 500 μl protoplast incubation buffer. Protoplasts were incubated in the dark at 30°C for 24 hr.

[0056] Kinase inhibitors (CalBiochem, San Diego, CA) at the concentration of 1 µM for staurosporine, 350 nM for SB 202190 and 1 µM for PD 98059, SB 203580 and SB 202474, when applicable, were included in the protoplast incubation buffer. The inhibitors did not change protoplast viability (data not shown).

Luciferase assay

[0057] Luciferase activity in protoplasts co-electroporated with the constructs under study and luciferase DNA as an internal control were determined for evaluation of transformation efficiency. Protoplasts were lysed in 200 µL of LUC extraction buffer (100 mM KPO_4, 1mM EDTA, 10% glycerol, 0.5% Triton X-100 and 7 mM β-merceptoethanol, pH 7.8). After microfuge centrifugation, the supernatant was collected and a 200 µL aliquot of LUC assay buffer (25mM Tricine, 15 mM $MgCl_2$, 5mM ATP, BSA 1mg/ml, and 5 µl β-merceptoethanol, pH 7.8) was added to each 20 µL aliquot followed by 100 µL of luciferin (0.5 mM) as substrate. The reaction was assayed in a luminometer as described (Matthews *et. al.*, 1995).

Quantitative RT-PCR

[0058] RT-PCR was as described above. The number of PCR cycles corresponded to the high end of the range in which a linear increase in products could he detected (generally 14-16 cycles were used). Reaction products were separated on 1.0 % agarose gels. Southern blot analysis was used to estimate levels of specific amplified products. Equivalence of cDNA in different samples was verified using PCR reactions for actin. Primers were designed for PCR according to published sequences for tomato PR-lbl, chitinase, Twit, ER5 and actin (Tornero *et al.*, 1997; Danhash *et al.*, 1993; O'Donnell *et al.*, 1998; Zegzouti *et al.* 1997; Moniz de Sa and Drouin, 1996).

[0059] Our results indicated that tomato PR1b1, chitinase and Twil genes were activated by tMEK2^{MUT}. This indicates that tMEK2 can mediate both pathogen and wound signals. Transient expression of the native tMEK2^{WT} gene had no effect on the expression of the three target genes (Figure 4), indicating that it is not errantly activated in the protoplast system.

Example 4: Induction of the Wound-Inducible Gene ER5

[0060] Since MAPK may be the point of convergence of the signal transduction pathways for fungal elicitors and mechanical stress (Romeis *et al.*, 1999) we also examined the induction of the wound-inducible gene, ER5 (Zegzouti *et al.*, 1997). Wounding was carried out by crushing leaves across the lamina and mid-vein using a blunt forceps. RNA was extracted after wounding for the indicated period of time. Fifteen µg of RNA was separated per lane on a denaturing formaldehyde gel. Following transfer to nylon membranes, the blot was hybridized with radio labeled fragment of tMEK2 coding region or fragment of ER5 coding region. Autoradiography was applied to visualize the hybridization signals (Sambrook *et al.*, 1989).

[0061] Wounding of tomato leaves induced both resident tMEK2 and ER5 genes, mRNA accumulation was detectable in 30 min and lasted for at least 4 hrs (Figure 5a). Transient expression of the mutant tMEK2^{MUT} gene in tomato protoplasts also activated ER5 (Figure 5b); however, tMEK2^{WT} did not (Figure 5b), showing that elevated transcription of tMEK2 alone was not sufficient for transmitting the wound signal to ER5.

Example 5: Different MAPKs downstream of tMEK2

[0062] To study divergence of the signal pathways downstream of tMEK2 the influence of tMAPK2^{MUT} expression in tomato protoplasts was examined in the presence of a broad protein kinase inhibitor (staurosporine) and inhibitors specific to the p38 class MAPK (SB 202190 or SB 203580). Staurosporine inhibited all four genes that were previously activated by tMEK2^{MUT}; whereas, inhibitors of p38 class MAPK inhibited the PR3 and ER5 genes but not PR1b1 or Twi1. Furthermore, no effects were observed with SB202474, an inert compound acting as a negative control for MAP kinase inhibition studies, or PD 98059, an inhibitor of the MAP kinase cascade which binds to MAPKKK at a site that blocks access to activating enzymes (Alessi *et al.*, 1995). The results, shown in Figure 6, are consistent with the divergence of signal pathway downstream of tMEK2. One of these pathways could include a p38 class MAPK.

Example 6: Disease Resistance

[0063] Tomato bacterial pathogen *Pseudomonas syringae* pv *tomato* was infiltrated into tomato leaves and the effect of inoculation was recorded 7 days after inoculation. A representative comparison of disease symptoms on a leaf from a wild-type plant and on a leaf from tMEK2^{MUT} transformed plant is shown in Figure 7.

Claims

1. A nucleic acid sequence encoding a derivative of a plant mitogen-activated protein kinase kinase, wherein said

derivative contains a negative charge at a core phosphorylation site of said protein kinase kinase.

2. The nucleic acid sequence of claim 1, wherein said derivative comprises replacement of one or more amino acids with an amino acid selected from the group consisting of: aspartic acid and glutamic acid.

3. The nucleic acid sequence of claim 2, wherein said derivative comprises replacement of one or more serine or threonine amino acids with an amino acid selected from the group consisting of : aspartic acid and glutamic acid.

4. The nucleic acid sequence of claim 3, wherein said nucleic acid sequence is isolated from the group consisting of: *Arabidopsis thaliana, Lycopersicum esculentum, Zea mais, N tabucum, D discoideum* and *Leischmania donovani.*

5. The nucleic acid sequence of claim 4, wherein said one or more threonine or serine amino acids are selected from the group consisting of:

Lycopersicum esculentum c.v. Bonny Best, tMEK 2: 219serine, 220threonine, 221 serine and 226threonine;
Arabidopsis thaliana, AtMAP2Kα: 220threonine, 226serine and 227serine;
A. thaliana, AtMKK4: 220threonine, 226serine and 227serine;
A. thaliana, AtMEK1: 219serine, 220threonine, 221serine, 222serine and 226serine;
L. esculentum, LeMEK1: 219serine, 220threonine, 221serine and 226threonine;
Zea mais, ZmMEK1: 219serine, 220serine and 226threonine;
A. thaliana, At MAP2Kβ: 218threonine, 220threonine and 226threonine;
N tabucum, NPK2: 219serine, 220serine and 226threonine;
A. thaliana, AtMKK3: 220serine and 226threonine;
D discoideum, DdMEK1, 220threonine, 222serine and 226threonine; and
Leischmania donovani, LPK: 220threonine, 224serine, 225serine and 226threonine;

wherein the amino acid numbering system is based on the tomato gene tMEK2.

6. The nucleic acid sequence of claim 5, wherein the nucleic acid is from tomato cv. Bonny Best, and wherein in the encoded derivative amino acids serine221 and threonine226 have been replaced with aspartic acid.

7. A derivative of a plant mitogen-activated protein kinase kinase, wherein said derivative contains a negative charge in a core phosphorylation site of said protein kinase kinase.

8. The derivative of claim 7, wherein said derivative comprises replacement of one or more amino acids with an amino acid selected from the group consisting of: aspartic acid and glutamic acid.

9. The derivative of claim 8, wherein said derivative comprises replacement of one or more serine or threonine amino acids with an amino acid selected from the group consisting of : aspartic acid and glutamic acid.

10. The derivative of claim 9, wherein the mitogen-activated protein kinase kinase is derived from plants selected from the group consisting of: *Arabidopsis thaliana, Lycopersicum esculentum, Zea mais, N tabucum, D discoideum* and *Leischmania donovani.*

11. The derivative of claim 10, wherein one or more of said serine or threonine amino acids are selected from the group consisting of:

Lycopersicumi esculentum c.v. Bonny Best, tMEK 2: 219serine, 220threonine, 221serine and 226threonine;
Arabidopsis thaliana, AtMAP2Kα: 220threonine, 226serine and 227serine;
A. thaliana, AtMKK4: 220threonine, 226serine and 227serine;
A. thaliana, AtMEK1: 219serine, 220threonine, 221serine, 222serine and 226serine;
L. esculentum, LeMEK1: 219serine, 220threonine, 221serine and 226threonine;
Zea mais, ZmMEK1: 219serine, 220serine and 226threonine;
A. thaliana, At MAP2Kβ: 218threonine, 220threonine and 226threonine;
N tabucum, NPK2: 219serine, 220serine and 226threonine;
A. thaliana, AtMKK3: 220serine and 226threonine;
D discoideum, DdMEK1, 220threonine, 222serine and 226threonine; and

Leischmania donovani, LPK: 220threonine, 224serine, 225serine and 226threonine;

wherein the amino acid numbering system is based on the tomato gene tMEK2.

12. The derivative of claim 11, wherein the derivative of a mitogen-activated protein kinase kinase is derived from tomato cv. Bonny Best, and wherein the amino acids serine221 and threonine226 have been replaced with aspartic acid.

13. A cloning vector comprising the nucleic acid sequence of claim 1.

14. A transgenic plant comprising the cloning vector of claim 13.

15. A transgenic plant comprising the nucleic acid sequence of claim 1.

16. A method of increasing disease resistance or enhancing stress tolerance in a plant by introducing into said plant a nucleic acid sequence encoding a derivative of a mitogen-activated protein kinase kinase, wherein said derivative contains a negative charge at a core phosphorylation site of said protein kinase kinase.

17. The method of claim 16, wherein said derivative comprises replacement of one or more amino acids with an amino acid selected from the group consisting of: aspartic acid and glutamic acid.

18. The method of claim 17, wherein said derivative comprises replacement of one or more serine or threonine amino acids with an amino acid selected from the group consisting of : aspartic acid and glutamic acid.

19. The method of claim 18, wherein said nucleic acid is isolated from the group consisting of: *Arabidopsis thaliana, Lycopersicum esculentun, Zea mais, N tabucum, D discoideum, Leischmania donovani, Drosophila melanogaste, Homo sapiens, R norvegicus, Saccharomyces cerevisiae* and *Candida albicans.*

20. The method of claim 19, wherein said one or more serine or threonine amino acids are selected from the group consisting of:

Lycopersicum esculentum, tMEK 2: 219serine, 220threonine, 221serine and 226threonine;
Arabidopsis thaliana, AtMAP2Kα: 220threonine, 226serine and 227serine;
A. thaliana, AtMKK4: 220threonine, 226serine and 227serine;
A. thaliana, AtMEK1: 219serine, 220threonine, 221serine, 222serine and 226serine;
L. esculentum, LeMEK1: 219serine, 220threonine, 221serine and 226threonine;
Zea mais, ZmMEK1: 219serine, 220serine and 226threonine;
A. thaliana, At MAP2Kβ: 218threonine, 220threonine and 226threonine;
N tabucum, NPK2: 219serine, 220serine and 226threonine;
A. thaliana, AtMKK3: 220serine and 226threonine;
D discoideum, DdMEK1, 220threonine, 222serine and 226threonine;
Leischmania donovani, LPK: 220threonine, 224serine, 225serine and 226threonine;
Drosophila melanogaste, HEP: 220serine and 226threonine; human, MEK1: 220serine and226serine;
R norvegicus, MEK5: 220serine and 226threonine;
Homo sapiens, MKK3: 220serine and 226threonine;
Saccharomyces cerevisiae, PBS2: 220serine and 226threonine;
S. cerevisiae, STE7: 220serine and 226threonine;
Candida albicans, HST 7: 220serine and 226threonine; and
S. cerevisiae, MKK1: 220serine, 225threonine and 226threonine;

wherein the amino acid numbering system is based on the tomato gene tMEK2.

21. The method of claim 20, wherein the nucleic acid is from tomato cv. Bonny Best, and wherein in the encoded derivative amino acids serine221 and threonine226 have been replaced with aspartic acid.

22. The method of claim 16, wherein said nucleic acid is introduced by a method selected from transformation and particle bombardment.

(54) Map kinase kinases (MEK)

(57) A mitogen-activated protein (MAP) kinase kinase gene, tMEK2, was isolated from tomato cv. Bonny Best. By mutagenesis, a permanently-active variant, $tMEK2^{MUT}$, was created. Both wild type tMEK2 and mutant $tMEK2^{MUT}$ were driven by a strong constitutive promoter, tCUPΔ, in a tomato protoplast transient expression system. Pathogenesis-related genes, PR1bl and PR3, and a wound-inducible gene, ER5, were activated by $tMEK2^{MUT}$ expression revealing the convergence of the signal transduction pathways for pathogen attack and mechanical stress at the level of MAPKK. Activation of biotic and abiotic stress response genes downstream of tMEK2 occurred through divergent pathways involving at least two classes of mitogen-activated protein kinase. This study shows that tMEK2 may play an important role in the interaction of signal transduction pathways that mediate responses to both biotic (eg disease) and abiotic (wound responsiveness) stresses.

CLAIMS INCURRING FEES

The present European patent application comprised at the time of filing more than ten claims.

☐ Only part of the claims have been paid within the prescribed time limit. The present European search report has been drawn up for the first ten claims and for those claims for which claims fees have been paid, namely claim(s):

☐ No claims fees have been paid within the prescribed time limit. The present European search report has been drawn up for the first ten claims.

LACK OF UNITY OF INVENTION

The Search Division considers that the present European patent application does not comply with the requirements of unity of invention and relates to several inventions or groups of inventions, namely:

see sheet B

☐ All further search fees have been paid within the fixed time limit. The present European search report has been drawn up for all claims.

☐ As all searchable claims could be searched without effort justifying an additional fee, the Search Division did not invite payment of any additional fee.

☐ Only part of the further search fees have been paid within the fixed time limit. The present European search report has been drawn up for those parts of the European patent application which relate to the inventions in respect of which search fees have been paid, namely claims:

☒ None of the further search fees have been paid within the fixed time limit. The present European search report has been drawn up for those parts of the European patent application which relate to the invention first mentioned in the claims, namely claims:

European Patent Office

LACK OF UNITY OF INVENTION SHEET B

Application Number
EP 00 30 7362

The Search Division considers that the present European patent application does not comply with the requirements of unity of invention and relates to several inventions or groups of inventions, namely:

1. Claims: 1-5,7-11,13-20,22 partially, 6,12,21 completely

   A nucleic acid sequence encoding a derivative of a plant mitogen-activated protein kinase kinase, wherein said derivative contains a negative charge at a core phosphorylation site of said protein kinase kinase; said nucleic acid sequence, wherein one or more threonine or serine amino acids are selected from Lycopersicon esculentum c.v. Bonny Best, tMEK2: 219 serine, 220 threonine, 221 serine and 226 threonine; a derivative of a plant mitogen-activated protein kinase kinase, wherein said derivative contains a negative charge in a core phosphorylation site of said protein kinase kinase; said derivative, wherein one or more threonine or serine amino acids are selected from Lycopersicon esculentum c.v. Bonny Best, tMEK2: 219 serine, 220 threonine, 221 serine and 226 threonine; a cloning vector comprising above nucleic acid; a transgenic plant comprising said cloning vector; a transgenic plant comprising above nucleic acid; a method of increasing disease resistance or enhancing stress tolerance in a plant by introducing into said plant a nucleic acid sequence encoding a derivative of a mitogen-activated protein kinase kinase, wherein said derivative contains a negative charge at a core phosphorylation site of said protein kinase kinase and said method, wherein one or more serine or threonine amino acids are selected from Lycopersicon esculentum, tMEK2: 219 serine, 220 threonine, 221 serine and 226 threonine.

2. Claims: 1-5,7-11,13-22 partially

   Invention no. 2 relates to subject-matter as defined above for "invention 1", with the exception, that invention no. 2 refers to AtMAP2Kalpha from Arabidopsis thaliana with the respective mutations at position 220 threonine, 226 serine and/or 227 serine (based on the amino acid numbering system of the tomato gene tMEK2) instead of tMEK2 from Lycopersicon esculentum c.v. Bonny Best.

3. Claims: 1-5,7-11,13-22 partially

   Invention no. 3 relates to subject-matter as defined above for "invention 1", with the exception, that invention no. 3 refers to AtMKK4 from Arabidopsis thaliana with the respective mutations at position 220 threonine, 226 serine and/or 227 serine (based on the amino acid numbering system of the tomato gene tMEK2) instead of tMEK2 from Lycopersicon esculentum c.v. Bonny Best.

European Patent Office

LACK OF UNITY OF INVENTION
SHEET B

Application Number
EP 00 30 7362

The Search Division considers that the present European patent application does not comply with the requirements of unity of invention and relates to several inventions or groups of inventions, namely:

4. Claims: 1-5,7-11,13-22 partially

Invention no. 4 relates to subject-matter as defined above for "invention 1", with the exception, that invention no. 4 refers to AtMEK1 from Arabidopsis thaliana with the respective mutations at position 219 serine, 220 threonine, 221 serine, 222 serine and/or 226 serine (based on the amino acid numbering system of the tomato gene tMEK2) instead of tMEK2 from Lycopersicon esculentum c.v. Bonny Best.

5. Claims: 1-5,7-11,13-22 partially

Invention no. 5 relates to subject-matter as defined above for "invention 1", with the exception, that invention no. 5 refers to LeMEK1 from Lycopersicon esculentum with the respective mutations at position 219 serine, 220 threonine, 221 serine and/or 226 threonine (based on the amino acid numbering system of the tomato gene tMEK2) instead of tMEK2 from Lycopersicon esculentum c.v. Bonny Best.

6. Claims: 1-5,7-11,13-22 partially

Invention no. 6 relates to subject-matter as defined above for "invention 1", with the exception, that invention no. 6 refers to ZmMEK1 from Zea mays with the respective mutations at position 219 serine, 220 serine and/or 226 threonine (based on the amino acid numbering system of the tomato gene tMEK2) instead of tMEK2 from Lycopersicon esculentum c.v. Bonny Best.

7. Claims: 1-5,7-11,13-22 partially

Invention no. 7 relates to subject-matter as defined above for "invention 1", with the exception, that invention no. 7 refers to AtMAP2Kbeta from Arabidopsis thaliana with the respective mutations at position 218 serine, 220 threonine and/or 226 threonine (based on the amino acid numbering system of the tomato gene tMEK2) instead of tMEK2 from Lycopersicon esculentum c.v. Bonny Best.

8. Claims: 1-5,7-11,13-22 partially

Invention no. 8 relates to subject-matter as defined above for "invention 1", with the exception, that invention no. 8 refers to NPK2 from Nicotiana tabacum with the respective mutations at position 219 serine, 220 serine and/or 226 serine (based on the amino acid numbering system of the tomato gene tMEK2) instead of tMEK2 from Lycopersicon

European Patent Office

LACK OF UNITY OF INVENTION
SHEET B

Application Number
EP 00 30 7362

The Search Division considers that the present European patent application does not comply with the requirements of unity of invention and relates to several inventions or groups of inventions, namely:

esculentum c.v. Bonny Best.

9. Claims: 1-5,7-11,13-22 partially

Invention no. 9 relates to subject-matter as defined above for "invention 1", with the exception, that invention no. 9 refers to AtMKK3 from Arabidopsis thaliana with the respective mutations at position 220 serine and/or 226 threonine (based on the amino acid numbering system of the tomato gene tMEK2) instead of tMEK2 from Lycopersicon esculentum c.v. Bonny Best.

10. Claims: 1-5,7-11,13-22 partially

Invention no. 10 relates to subject-matter as defined above for "invention 1", with the exception, that invention no. 10 refers to DdMEK1 from Dictyostelium discoideum with the respective mutations at position 220 threonine, 222 serine and/or 226 threonine (based on the amino acid numbering system of the tomato gene tMEK2) instead of tMEK2 from Lycopersicon esculentum c.v. Bonny Best.

11. Claims: 1-5,7-11,13-22 partially

Invention no. 11 relates to subject-matter as defined above for "invention 1", with the exception, that invention no. 11 refers to LPK from Leischmania donovani with the respective mutations at position 220 threonine, 224 serine, 225 serine and/or 226 threonine (based on the amino acid numbering system of the tomato gene tMEK2) instead of tMEK2 from Lycopersicon esculentum c.v. Bonny Best.

12. Claims: 16-20,22 partially

A method of increasing disease resistance or enhancing stress tolerance in a plant by introducing into said plant a nucleic acid encoding a derivative of a mitogen-activated protein kinase kinase, wherein said derivative contains a negative charge at a core phosphorylation site of said protein kinase kinase and said method wherein said nucleic acid is isolated from the group consisting of: Drosophila melanogaster, Homo sapiens, Rattus norwegicus, Saccharomyces cerevisiae and Candida albicans.

ANNEX TO THE EUROPEAN SEARCH REPORT ON EUROPEAN PATENT APPLICATION NO. EP 00 30 7362

This annex lists the patent family members relating to the patent documents cited in the above-mentioned European search report.
The members are as contained in the European Patent Office EDP file on
The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information.
